# Data Visualization in R Programming: A Practical Introduction

#### Nith Kosal

May 12, 2021

#### Data Visualization Notes

This is a outcome in PDF file from RMarkdown project template to accompany training with *Data Visualization*. You can use it to take notes, write your code, and produce a good-looking, reproducible document that records the work you have done. At the very top of the file is a section of *metadata*, or information about what the file is and what it does. The metadata is delimited by three dashes at the start and another three at the end. You should change the title, author, and date to the values that suit you. Keep the output line as it is for now, however. Each line in the metadata has a structure. First the *key* ("title", "author", etc), then a colon, and then the *value* associated with the key.

#### This Document is an RMarkdown File

This is an R Markdown document. Markdown is a simple formatting syntax for authoring HTML, PDF, and MS Word documents. For more details on using R Markdown see http://rmarkdown.rstudio.com.

When you click the **Knit** button a document will be generated that includes both content as well as the output of any embedded R code chunks within the document. A *code chunk* is a specially delimited section of the file. You can add one by moving the cursor to a blank line choosing Code > Insert Chunk from the RStudio menu. When you do, an empty chunk will appear in your file.

Code chunks are delimited by three backticks (found to the left of the 1 key on US and UK keyboards) at the start and end. The opening backticks also have a pair of braces and the letter r, to indicate what language the chunk is written in. You write your code inside the code chunks. Write your notes and other material around them, as here.

#### Things to know about R

Any new piece of software takes a bit of getting used to. This is especially true when using an IDE to work in a language like R.

#### Everything has a name

In R, everything you deal with has a name. You refer to things by their names as you examine, use, or modify them. Named entities include variables (like x, or y), data that you have loaded (like my\_data), and functions that you use. (More about functions momentarily.) You will spend a lot of time talking about, creating, referring to, and modifying things with names.

Some names are forbidden. These include reserved words like FALSE and TRUE, core programming words like Inf, for, else, break, function, and words for special entities like NA and NaN. (These last two are codes designating missing data and "Not a Number", respectively.) You probably won't use these names by accident, but it's good do know that they are not allowed.

Some names you should not use, even if they are technically permitted. These are mostly words that are already in use for objects or functions that form part of the core of R. These include the names of

basic functions like q() or c(), common statistical functions like mean(), range() or var(), and built-in mathematical constants like pi.

Names in R are case sensitive, not much difficult from others programming languages. The object my\_data is not the same as the object My\_Data. When choosing names for things, be concise, consistent, and informative. Follow the style of the tidyverse and name things in lower case, separating words with the underscore character, \_, as needed. Do not use spaces when naming things, including variables in your data.

#### Everything is an object

Some objects are built in to R, some are added via libraries, and some are created by the user. But almost everything is some kind of object. The code you write will create, manipulate, and use named objects as a matter of course. We can start immediately. Let's create a vector of numbers. The command c() is a function. It's short for "combine" or "concatenate". It will take a sequence of comma-separated things inside the parentheses and join them together into a vector where each element is still individually accessible.

```
c(1, 2, 3, 1, 3, 2020, 2021)
## [1]
                               3 2020 2021
# create object's name
my_numbers \leftarrow c(1, 2, 3, 1, 3, 2020, 2021)
futureforum_team <- c("Dara", "Soriya", "Sokhouy", "Kimly", "Heang", "Samnang")</pre>
y <- 1:9
# call for object that we want to see
futureforum_team
## [1] "Dara"
                  "Soriya" "Sokhouy" "Kimly"
                                                 "Heang"
                                                           "Samnang"

#### Load Libraries

To begin we must load some libraries we will be using. If we do not load them, R will not be able to find the functions contained in these libraries. But for the first time with R Programming, you should install library packages that common use.

Here, the braces at the start of the code chunk have some additional options set in them. There is the language, r, as before. This is required. Then there is the word setup, which is a label for your code chunk. Labels are useful to briefly say what the chunk does. Label names must be unique (no two chunks in the same document can have the same label) and cannot contain spaces. Then, after the comma, an option is set: include=FALSE. This tells R to run this code but not to include the output in the final document.

If you have not installed these required libraries yet, make sure you have an internet connection and install them now.

```
# to install these packages, in the line above.
# basic method that common use for new learner
install.packages("tidyverse")
install.packages("broom")
# advanced method
my_packages <- c("tidyverse", "broom", "coefplot", "cowplot", "drat", "fs",
                 "gapminder", "GGally", "ggrepel", "ggridges", "gridExtra",
                 "here", "interplot", "margins", "maps", "mapproj",
                 "mapdata", "MASS", "quantreg", "rlang", "scales",
                 "survey", "srvyr", "viridis", "viridisLite", "devtools")
# R Studio should then download and install these packages for you.
install.packages(my_packages, repos = "http://cran.rstudio.com")
# load libraries for use
# basic method
library(gapminder)
library(here)
library(tidyverse)
# advanced method
Packages <- my_packages
```

```
Packages <- c("tidyverse", "broom", "coefplot", "cowplot", "drat", "fs",
              "gapminder", "maps", "mapproj", "survey", "srvyr", "viridis",
              "viridisLite", "devtools")
lapply(Packages, library, character.only = TRUE)
# to update our package
update.packages()
# to know which pack need an update
old.packages()
# to know which packages are being loaded
search()
# request for help
?hist
help(package = "tidyverse")
example("hist")
# use ?? to search by keyword
??regression
```

So let we go with some datasets on R

```
\# call the dataset from R mtcars
```

```

# Educational Attainment by Race GSS 1976–2016

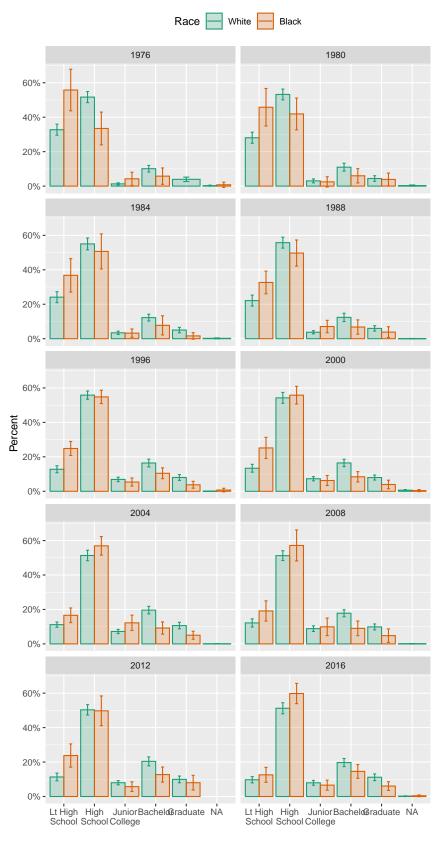

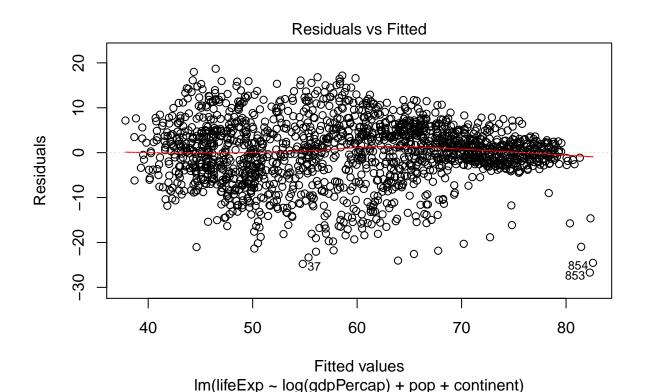

Figure 16: Weighted estimates of educational attainment for Whites and Blacks, GSS selected years 1976-2016. Faceting barplots is often a bad idea, and the more facets there are the worse an idea it is. With a small-multiple plot the viewer wants to compare across panels (in this case, over time), but this is difficult to do when the data inside the panels are categorical comparisons shown as bars (in this case, education level by group).

#### Default plots for models

```
out <- lm(formula = lifeExp ~ log(gdpPercap) + pop + continent, data = gapminder)
plot(out, which = c(1,2), ask=FALSE)</pre>
```
